

# Automatically Fuzzing Routing Protocols

**Martin Vivian**, Olivier Bonaventure

IFIP 2026, Lugano 26 May

This work was supported by the Walloon Region of Belgium under the conventions n°2110186 (Cyber Excellence)

# Why Test Routing Protocols?

- Critical infrastructure
- Crashable via malformed messages
- Proven by real incidents

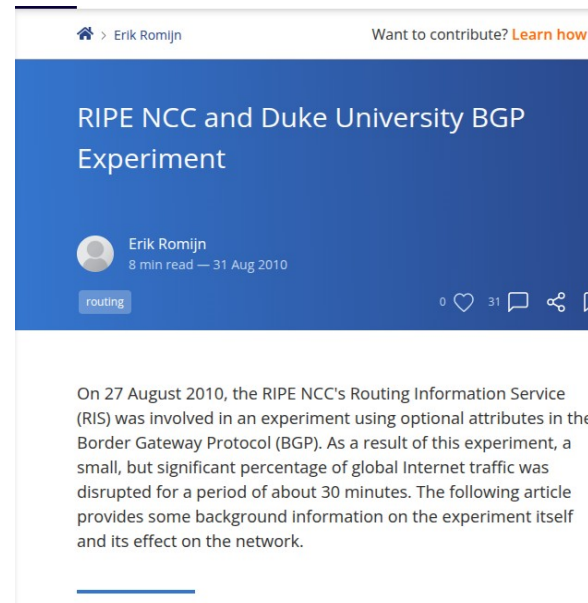

**NIST** NATIONAL VULNERABILITY DATABASE NVD

VULNERABILITIES

## CVE-2024-20406 Detail

### Description

A vulnerability in the segment routing feature for the Intermediate System-to-Intermediate System (IS-IS) protocol of Cisco IOS XR Software could allow an unauthenticated, adjacent attacker to cause a denial of service (DoS) condition on an affected device. This vulnerability is due to insufficient input validation of ingress IS-IS packets. An attacker could exploit this

routing

0 hearts 31 comments

On 27 August 2010, the RIPE NCC's Routing Information Service (RIS) was involved in an experiment using optional attributes in the Border Gateway Protocol (BGP). As a result of this experiment, a small, but significant percentage of global Internet traffic was disrupted for a period of about 30 minutes. The following article provides some background information on the experiment itself and its effect on the network.

Los Angeles Times

TECHNOLOGY AND THE INTERNET

### AT&T; Long-Distance Calls Blocked : Communications: About half the calls that customers were trying to make were affected. The software problem took hours to correct.

TIMES STAFF WRITER

**NEW YORK** — If you tried to reach out on Monday, chances were about even that you did not touch anyone.

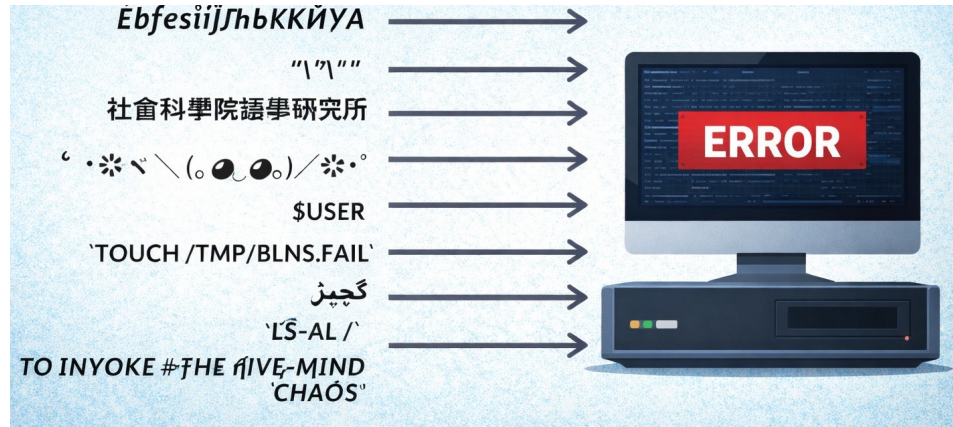

# Problem

- Network communication
- Proprietary
- Non-standard format
- Checksum

**Can we test routing protocols without knowing their format?**

# What is fuzzing ?

Automated testing with pseudo-random inputs to find crashes, bugs

## Protocols

- **Fuzzing approaches:** Black-box, Grey-box, White-box
- **Typical challenges:** proprietary formats, complex structure, high message rate, limited visibility into implementations

# Fuzzing state of the art

## Protocol fuzzing

- MitM

- Stateful

## Unsupported by existing tools

- Non-text-based messages
- No clear request-response sequences
- Specifics for one implementation

# We propose two tools

## **PRO**tocol Structure Extractor (**PROSE**)

- Checksum
- Header Length parameter
- Type and Length from TLV

## **M**utation & **S**tress Engine (**MUSE**)

- Fuzzing tool
- Generate new input to the target
- Priorities mutation on value field

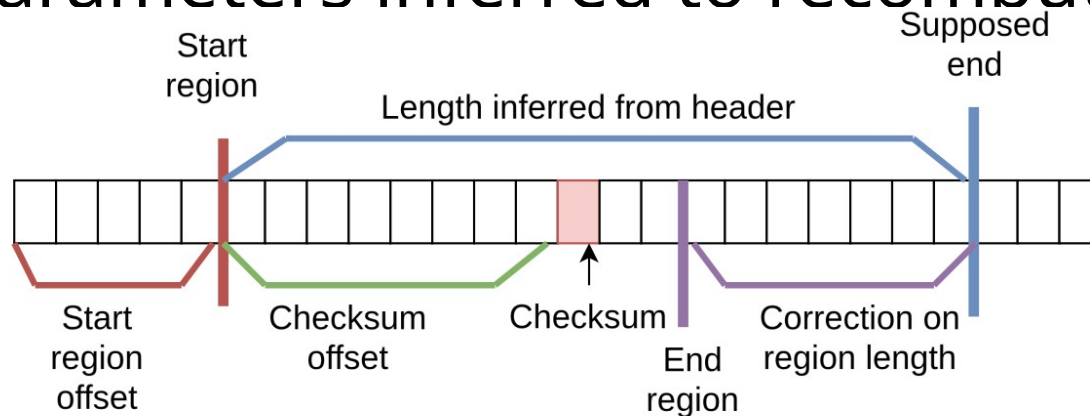

=> **PROSE** infers a structure reused by **MUSE** for fuzzing

# PROSE

- Locate length field
- Inferring the parameters for checksum
- Detecting where TLV structures begin
- Automatic exploration of different hypotheses to find the Type and Length sizes
- Return a set of Type-Length

# Header Length field & Checksum inference

- **BinaryInferno[\*]** only helps detect the header length field  
=> Avoid misinterpretation
- Invalid checksums cause immediate rejection
- Test common checksums (Fletcher-16, Internet checksum)
- Reuse inferred length in checksum computation
- 3 parameters inferred to recompute checksum

[\*]Chandler, J., Wick, A., & Fisher, K. (2023, March). BinaryInferno: A Semantic-Driven Approach to Field Inference for Binary Message Formats. In *NDSS*.

# PROSE: Hypothesis on TLV structure

- Type followed by Length then Value
- Fixed sizes for T and L
- No padding
- Length interpreted as several bytes

# PROSE: Algorithm to find the TLV

- Infer the first TLV to discover the others
- Jump through packets using inferred sizes

## Example

1. The algorithm tests TL 32
2. After 2, it tests TL 14
3. After 4, it tests TL 74
4. After 4, it is out of bound

1. The algorithm tests TL 32
2. After 2, it tests TL14
3. After 4, it tests TL 73
4. After 3, it reach TL end

- Select the candidate position that works the most
- Infer remaining TLVs through successive jumps

# Sub-TLV inference

## Challenge

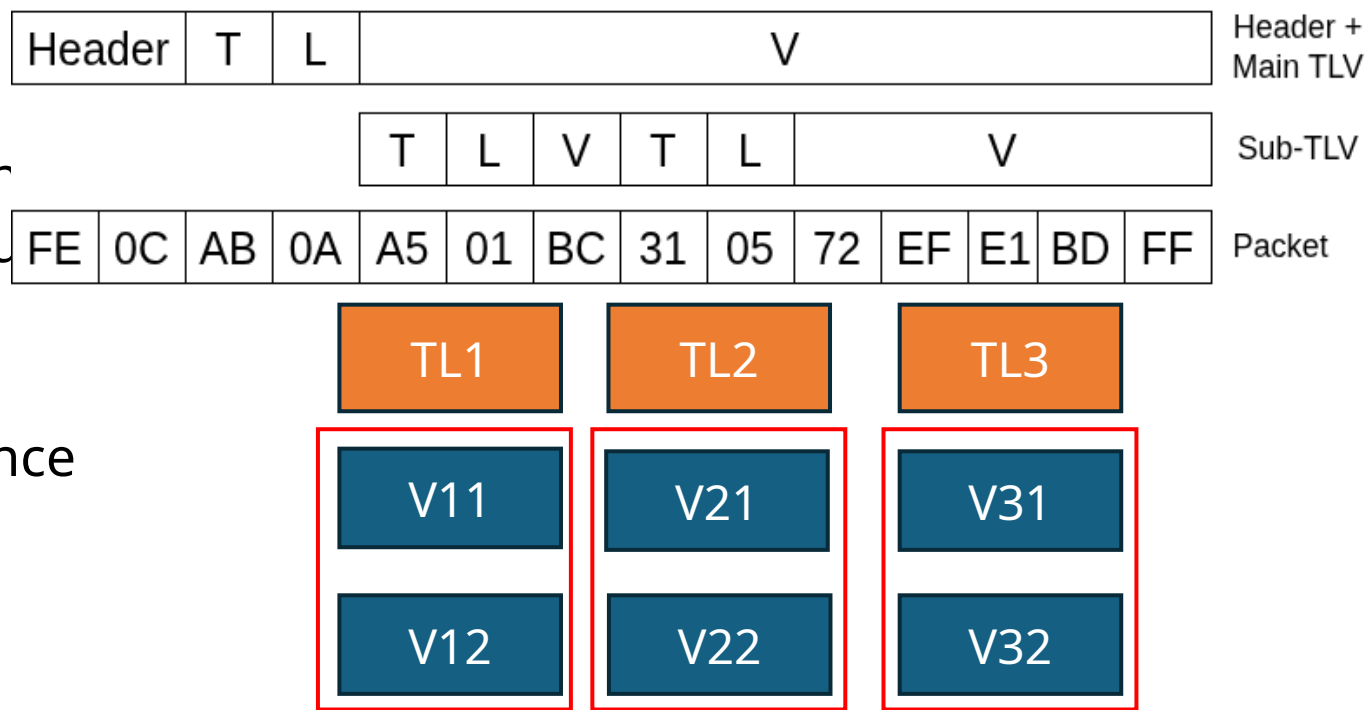

- Jump inference misses nested TLV structures
- Same length does not imply same internal structure
- Sub-TLV may start at different offsets

## Idea

Messages sharing the same TL pattern are likely to contain similar sub-structures

## Approach

- Group packets by inferred TL sequence
- Extract corresponding Value fields
- Re-run inference inside each cluster

# Type and Length size inference

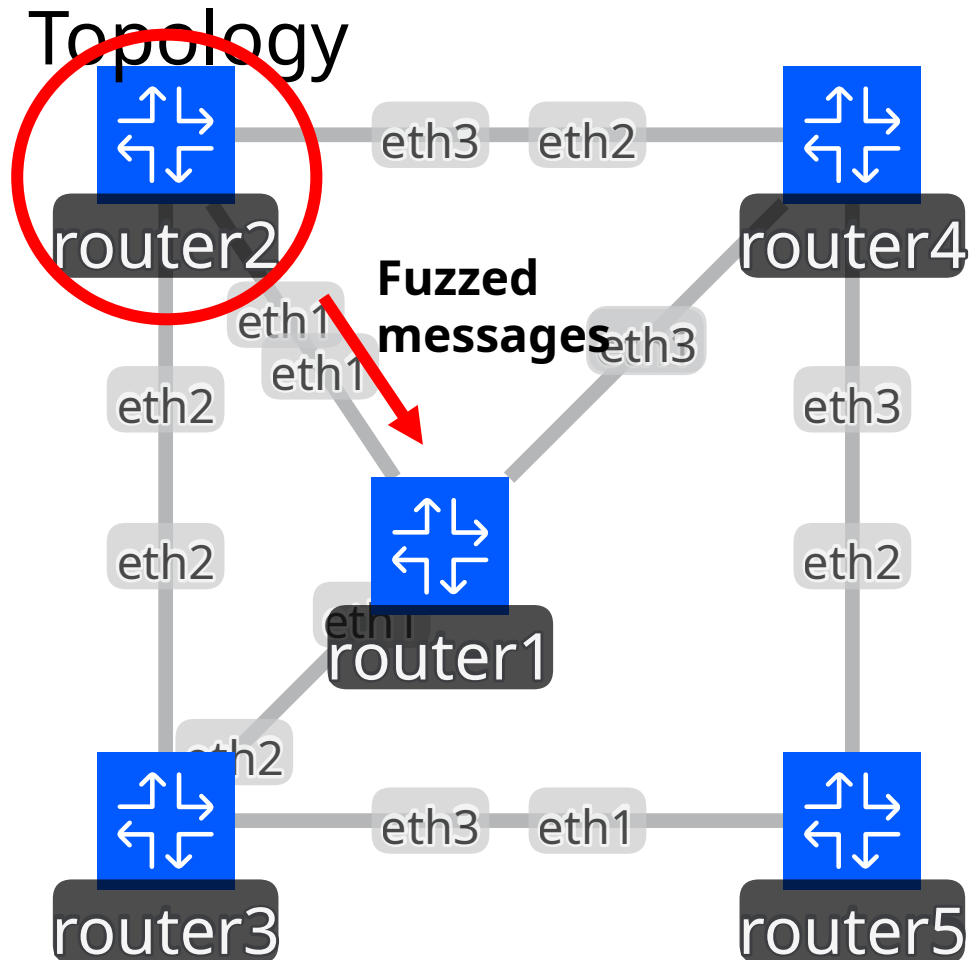

## **Problem**

- Type and Length sizes are unknown
- Length decoding depends on assumed field sizes

## **Solution**

- Re-run the algorithm with different Type/Length size assumptions
- Evaluate each configuration
- Keep the one producing the largest set of TL pairs
- Default maximum size: 5 bytes

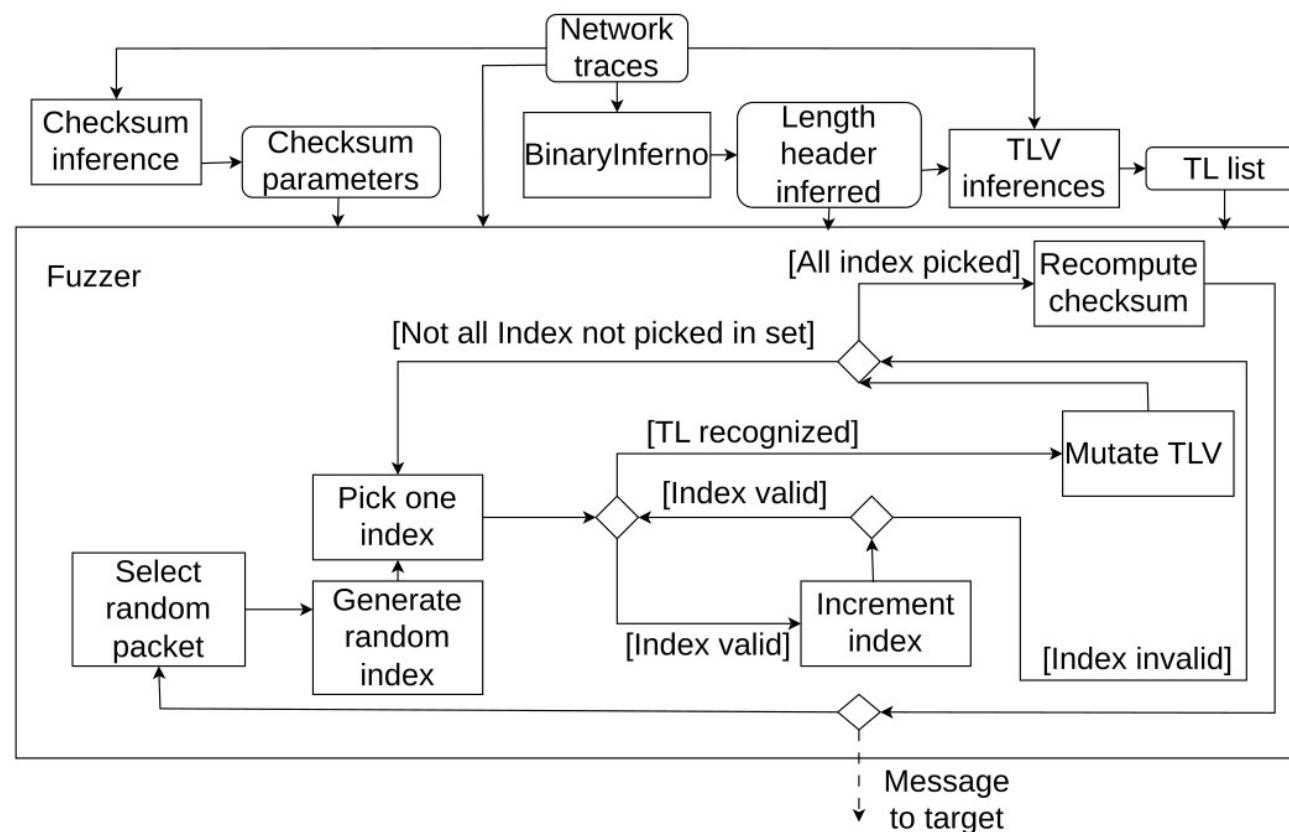

# Fuzzing on routing protocols with MUSE

- MUSE runs on router2
- Constructs messages from PCAP traces
- Sends messages to router1 using inferred TLV structure (PROSE)

# How messages are constructed

- **MUSE** receives parameters inferred by **PROSE** (checksum, length header, TL list)
- Select a random packet from the inference dataset
- Find TL structure in the packet
- Mutate Value field (and optionally Type/Length)
- Recompute dependent fields (Length, checksum)
- Send mutated packet

# Targets for fuzzing

## **FRRouting 10.3**

### **EIGRP ( Enhanced Interior Gateway Routing Protocol )**

- RFC 7868
- Developed by Cisco
- Proprietary until 2013
- Distance Vector

### **Babel**

- RFC 8966
- Distance Vector
- More recent

### **IS-IS (Intermediate System to Intermediate System)**

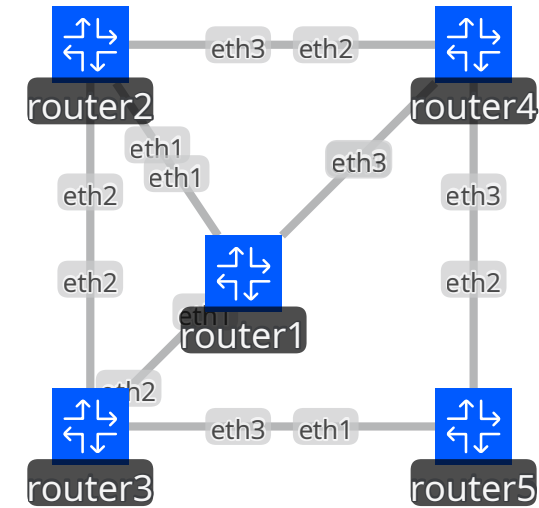

- ISO/IEC 10589:2002
- Link-State routing protocol
- Widely used by ISP

# PROSE evaluation

## Collecting traces

- Emulation with containerlab
- Dataset with 120 packets
- All optional protocol features
- Same topology for IS-IS, EIGRP, Babel

## Results

- Checksum, TLV, length field in header correctly found in the protocols
- Inference with TLV only works but for sub-TLV

Protocols	ISIS	Babel	EIGRP
Precision	68.57%	100%	100%
Recall	75%	88.89%	100%

# MUSE evaluation

## Setup

- Compare **MUSE** VS Random Fuzzer
- Line coverage measured on TLV parsing code

## Results

- **MUSE** reaches higher median line coverage
- Random mutations rejected earlier

Packets	IS-IS		EIGRP		Babel	
	<b>MUSE</b>	Random Fuzzer	<b>MUSE</b>	Random Fuzzer	<b>MUSE</b>	Random Fuzzer
100	32.94	30.50	59.91	55.06	65.16	61.45
500	33.01	30.50	59.91	56.27	74.93	65.34
1000	35.04	32.73	59.91	56.68	76.70	71.97
2000	/	32.73	59.91	57.89	81.34	74.26

# Results fuzzing on routing protocols

## Test on FRRouting version 10.3

### EIGRP

- Infinite loop
  - CPU saturated (~100%)
  - Hello packet with a valid Hello packet with valid TL + excessive padding (0x00) → loop increment = 0
- Read from unallocated memory
  - Potential crash, issue detected with Valgrind
  - Same problem but with other value of increment it access to unallocated memory
- Abort via assertion
  - Process restart
  - Two different assertions observed, likely same root cause

### IS-IS

- Process restart with a specific input and crash after 2-3 seconds
- => Issues reported to FRRouting dev, two first already fixed

# Limitations and potential extensions

- Not stream-based protocols
- More difficulties to infer sub-TLV
- Test on more protocols

# Conclusion

Source code :  
[https://github.com/Martinviv/fuzzing\\_routing\\_protocols](https://github.com/Martinviv/fuzzing_routing_protocols)

## Tested routing protocols

- Developed **PROSE** tool
- Developed **MUSE** tool
- Inferred header, checksum and TLV structure
- Works successfully on EIGRP, IS-IS, Babel
- Found issues in open sources implementation of routing protocols

## Future work

- Evaluate the tool on more protocols
- Extended for protocols bytestream like BGP

# Routing

- Control plane
  - Runs routing protocols (OSPF,EIGRP, IS-IS...)
  - Calculates and updates the routing table
  - Responds to network changes
  - Determines the best path for traffic
- Data plane
  - Uses the routing table to forward packets
