Motivations for Multihoming

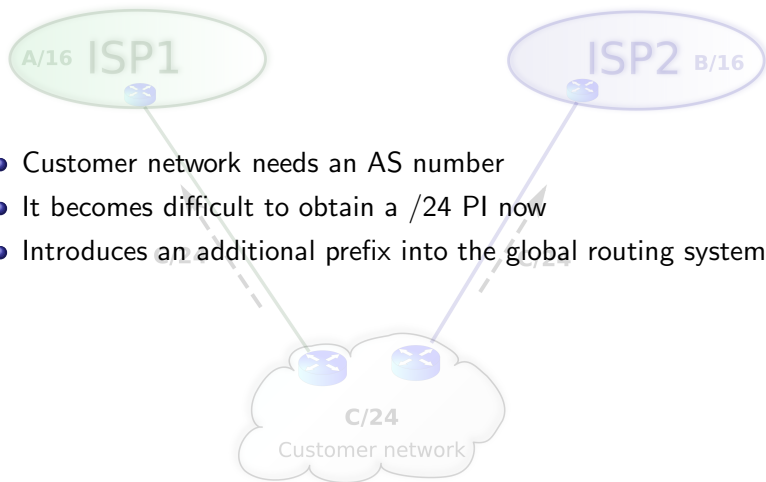

- 1 Introduction
 - Multihoming with IPv4
 - Motivations for IPv6
 - IPv6 addresses
- 2 The Shim6 protocol
- 3 LinShim6 implementation for Linux
- 4 Conclusion

Using a Provider Independent (PI) IPv4 address block

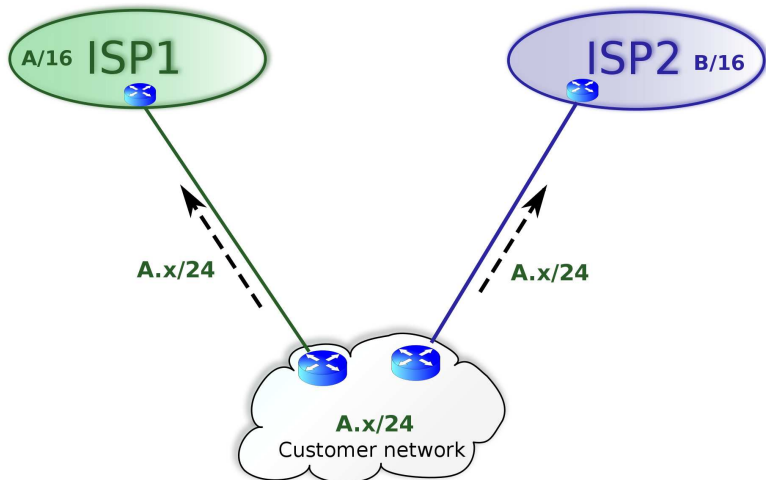

Using a Provider Independent (PI) IPv4 address block

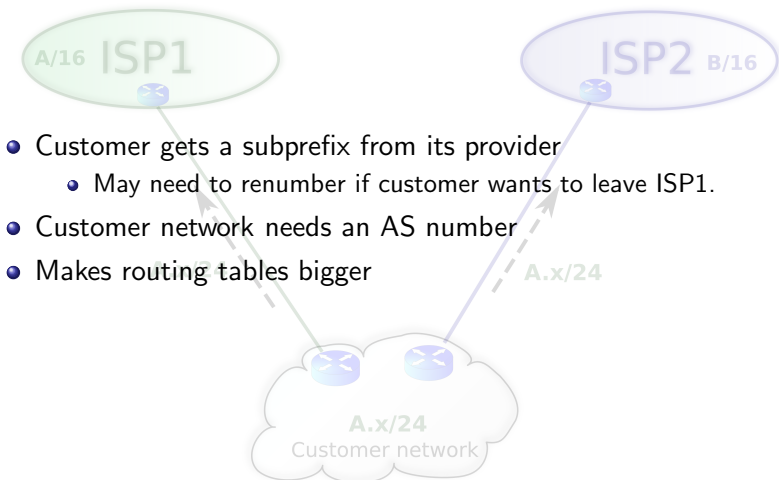

- Customer network needs an AS number
- It becomes difficult to obtain a /24 PI now
- Introduces an additional prefix into the global routing system

Réf.: Abley et al., RFC4116, *IPv4 multihoming practices and limitations*

Using a Provider Aggregatable (PA) IPv4 address block

Using a Provider Aggregatable (PA) IPv4 address block

- Customer gets a subprefix from its provider
 - May need to renumber if customer wants to leave ISP1.
- Customer network needs an AS number
- Makes routing tables bigger

Réf.: Abley et al., RFC4116, *IPv4 multihoming practices and limitations*

LIFETIME FOR IPV4 ADDRESSES IS PROJECTED TO FINISH ON 1/1/11

As of 1/1/11, all the new IP addresses will be allocated on IPv6

Monterrey, Mexico, June 21th, 2007. - According to forecasts of some investigators, in the next three years the central pool of Internet Protocol addresses of the present version 4, IPv4 will be depleted, so from January 1st, of 2011, NIC Mexico will not be able to allocate anymore IPv4 addresses and will only assign IP addresses in version 6 of the Internet Protocol (IPv6).

NIC Mexico altogether with LACNIC, organism in charge of managing the allocations of Internet Resources in the region of Latin America, has announced to the Internet Community about the depletion of IPv4 addresses and asks them to take the necessary measures to migrate to IPv6.

The objective of this announcement is to warn the Internet Community so that suitable measures could be taken before the Internet Protocol takes order because of the depletion of IPv4 addresses, particularly about to the Internet connection through mobile devices and other nontraditional devices, said the CEO.

According to NIC Mexico, it is recommendable for companies, governments and institutions, take the proper considerations by analyzing their future needs on new allocations, and if being necessary take any and all measurements to migrate to version six of this protocol (IPv6). It is convenient to emphasize that at the present time the allocation of Internet Resources addresses of IPv6 is free of charge.

It is recommendable to take advantage of time and start reviewing many of the critical applications that some

Other expectations for IPv6

- Lower load of Internet routing tables
- Less packet processing in the core of the Internet
 - Push state towards the edges
- No more NATs: IP address for everyone
- Improved security, mobility and **multihoming**

IPv6 address format

PA vs PI addresses

- **PI:** Provider Independent addresses
 - The site announces its PI address set through BGP
 - If multihomed: multiple BGP announcements
 - Global announcements of PI prefixes
 - What if many sites get multihomed ?
 - ➔ Scalability problem
- **PA:** Provider Aggregatable addresses
 - The site receives a subset of its provider's addresses
 - Only the provider announces its address set through BGP
 - If multihomed : The site receives several address blocks

PA vs PI addresses

The case of UCLouvain

- Two providers, thus two global routing prefixes:
 - 2001:6a8:3080: Provider is Belnet
 - 2001:6f8:31c: Provider is Easynet
- Several subnetworks:
 - 2: Staff
 - 3: Servers
 - 4: Experiments
 - 2001: Wifi staff

A typical laptop in our department

Interface 0 (to wired network)

The diagram shows a horizontal bar representing a laptop. The bar is divided into three segments by two vertical lines. A white rectangular box with a black border is centered over the middle segment, containing the text 'Interface 0 (to wired network)'. The bar has a light blue top half and a dark blue bottom half, with a white horizontal line separating them.

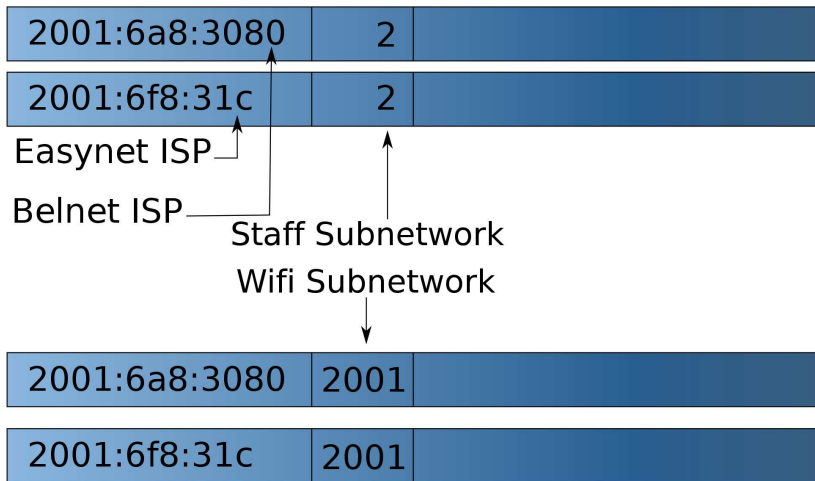

Interface 1 (to wireless network)

The diagram shows a horizontal bar representing a laptop, identical in structure to the one above. A white rectangular box with a black border is centered over the middle segment, containing the text 'Interface 1 (to wireless network)'. The bar has a light blue top half and a dark blue bottom half, with a white horizontal line separating them.

PA implications

- PA addresses reduce the load for the BGP system. . .
- . . . But it pushes new responsibilities to the end system
 - ➔ Failover from one address to another working one
 - ➔ Load balancing
- Those are completely managed by the network in v4.
- In v6, **part** is now managed by the end-system
 - ➔ We need to upgrade the end-hosts !

End-host upgrade: the problem

- Current applications assume one $\langle \text{src}, \text{dest} \rangle$ address pair for a given communication
- They also assume that the network ensures failover if a problem happens somewhere.
→ **How to manage failover in the end-host without changing applications ?**

End-host upgrade: the problem

- Current applications assume one $\langle \text{src}, \text{dest} \rangle$ address pair for a given communication
- They also assume that the network ensures failover if a problem happens somewhere.
➔ **How to manage failover in the end-host without changing applications ?**

End-host upgrade: How to do it ?

- To detect failures: Monitor the communications
- To switch to a working path: Change the current address pair

End-host upgrade: a solution ?

End-host upgrade: a solution ?

Why ?

- An IP address has currently a double semantics: **Locator** and **Identifier**
 - Locator: The IP address is used to forward the packet towards its destination.
 - ➔ Changing the IP address has the effect of changing the path.
 - Identifier: The IP address is used as part of the TCP context identifier
 - ➔ **Changing the IP address has the effect of breaking TCP connexions**

 - Identifier: The IP address is used as part of the TCP context identifier
 - ➔ **Changing the IP address has the effect of breaking TCP connexions**

The Shim6 proposal

- Separate the two semantics
 - The transport and application layer see an identifier
 - The network and data link layer see a locator.
 - A new Shim layer **rewrites** identifiers to replace them with locators
 - The same Shim layer **rewrites** locators to replace them with identifiers

The Shim6 proposal

New solutions - new problems: the time shifting attack

How to avoid that ?

- Sign the message with a private key
- Put the public key in the message
- The receiver verifies the signature thanks to the provided public key.

How to ensure that the public key is not replaced by the attacker ?

How to avoid that ?

How to avoid that ?

- Sign the message with a private key
- Put the public key in the message
- The receiver verifies the signature thanks to the provided public key.

How to ensure that the public key is not replaced by the attacker ?

How to ensure public key authenticity ?

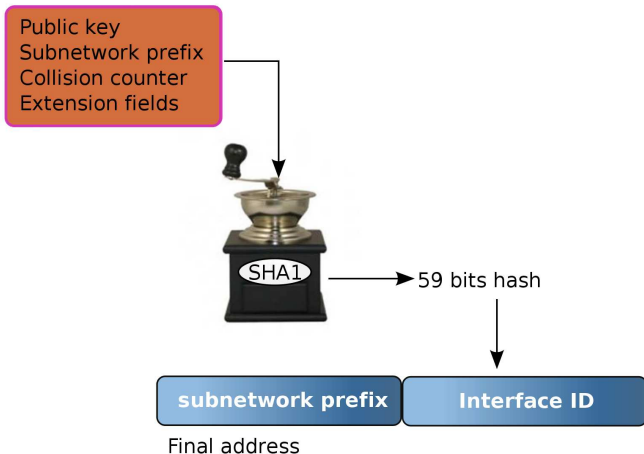

- Classical solution: Use a certificate, signed by a trusted third-party
 - ➔ We cannot give a certificate to everyone in the Internet !
- We have long addresses anyway: let's embed the public key inside the address. . .

How to ensure public key authenticity ?

- We have long addresses anyway: let's embed the public key inside the address. . .

Cryptographically Generated Addresses (CGAs)

A first proposal:

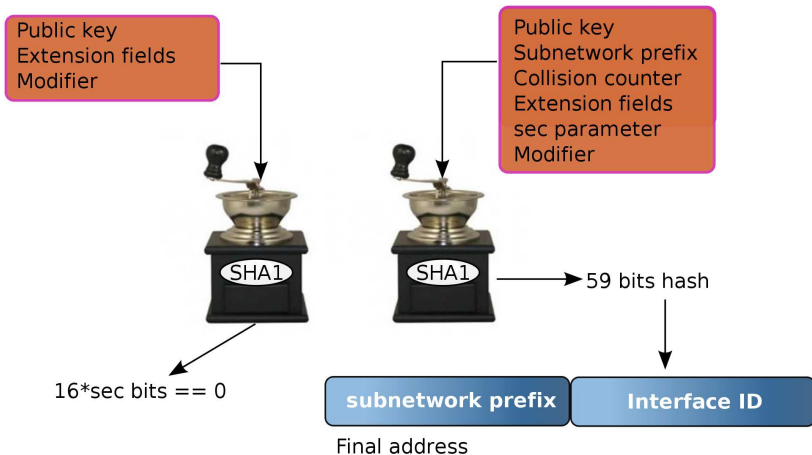

Cryptographically Generated Addresses (CGAs)

- 59 bits is too short a hash to ensure that it won't be broken.
- Solution: *artificially* extend the hash length
 - Compute a second hash, with an additional input called *modifier*
 - Require that n bits be 0 in the result
 - increment the modifier and retry the hash computation until n bits are zero
 - ➔ Brute-force attack of our own address...
 - ➔ But we are $\mathcal{O}(2^{59})$ in advance over our attacker !

Cryptographically Generated Addresses (CGAs)

- 59 bits is too short a hash to ensure that it won't be broken.

 - Compute a second hash, with an additional input called *modifier*
 - Require that n bits be 0 in the result
 - increment the modifier and retry the hash computation until n bits are zero
 - ➔ Brute-force attack of our own address...
 - ➔ But we are $\mathcal{O}(2^{59})$ in advance over our attacker !

Cryptographically Generated Addresses (CGAs)

Cryptographically Generated Addresses (CGAs): the cost

- Generation (owner): $\mathcal{O}(2^{16*sec})$
- Breaking the address (attacker): $\mathcal{O}(2^{59+16*sec})$
- Verification (receiver): $\mathcal{O}(1)$
 - ➔ Two hash computations

Hash Based Addresses

- Similar to CGA addresses, but lighter.
- Same input as for CGAs
- Public key is a random number
- Extension field is the list of prefixes.
- No signature needed, addresses validated by the fact that they are all bound together.

HBA vs CGA

- CGA is computationally more expensive (key generation, signature).
- But HBA does not allow adding addresses later
 - All prefixes are included in the hash
 - Adding one prefix results in changing **all** addresses
- Tradeoff: CGA-compatible HBAs
 - A public key is used for generation, but the multi-prefix extension is included
 - Initial address set is announced through HBA
 - Additional addresses can be generated and announced using CGA.

HBA vs CGA: efficiency

Comparison of security mechanisms

- 1 Introduction
- 2 The Shim6 protocol
- 3 LinShim6 implementation for Linux**
- 4 Conclusion

Want to play ?

- LinShim6 can be downloaded at <http://in1.info.ucl.ac.be/LinShim6>
- Currently the implementation that best supports the specification
- Allows using CGA/HBA/CGA-compatible HBAs.
- Can be easily installed in Ubuntu thanks to .deb packages.
- No special configuration needed (except for special purposes).

- 1 Introduction
- 2 The Shim6 protocol
- 3 LinShim6 implementation for Linux
- 4 Conclusion**

Shim6 challenges

- Bootstrap problem: **both** ends need to support Shim6 in order to get any benefit
 - If you install Shim6 now, almost no peer will know about it. . .
 - But if it gets installed in standard distributions, the whole world would have it at once.
- Load balancing: The end-host is now responsible for part of it. How to give control back to the network ?
 - Use a central server that hints the end-hosts ? (IDIPS)
 - Allow routers to re-rewrite Shim6 packets to enforce network policy ?

Shim6 challenges

- Renumbering: All ongoing communications are broken in case of renumbering
 - We would probably need a separate identifier space to solve that.
- Transport level multipath: Extending Shim6 to make it a path manager for transport protocols ?
- Mobility: To be investigated

Questions ?
